Adverse events after age and serverity in Milne et al(1)

All cases in the right 3 columns are only unique cases.

Review references are worked out in de table rows below and only unique items are considered!

= onjuiste indicatie = mild adverse effect = moderate adverse effect = severe adverse effect

The evidence based statement of Olson and al is casuistically build on Corso 2020, Green 2019, Milne 2022, L' Ecuyer 1959, Ziv 1983, Borusiak 2010, Zimmerman 1978, Koch 1998(2). See tables 2 & 3 in the study and cited paragraph on adverse effects down here below.

- *Adverse event analysis*

We recommended and require systematic reporting of mild or severe adverse events in future research [57]. The relative risk of a severe adverse event could not be determined from reported data and incidence of mild transient symptoms ranges from 0.3% (95% CI 0.06 to 1.82) to 22.22% (95% CI 6.32 to 54.74) [4,17]. It was not possible to provide an overall conclusion about the safety of spinal manipulation or mobilisation; small, randomised trials will not pick up uncommon events [17]. Adverse events were reported [17] as *severe* in infant torticollis [33,34] child neck-back pain [31,32], child headache [35,36]; and reported as *moderate* for infant colic [39]; and child/adolescent nocturnal enur-

Table 1. *Descriptions of reactions from PSMT reported by parents*

Number	Sex	Age at time of reaction (wk)	Description of reaction
1	Male	8	After the first treatment of cervical spine SMT for the treatment of infant colic, the parents telephoned to say the infant was not feeding well and was mildly distressed. The tutor told the parents to monitor the infant closely and to take him to the general practitioner for examination if he did not begin to feed normally within a few hours. The next day the parents called to say that the infant was fine and they resumed care at the clinic for their child.
2	Female	8	After the fourth treatment of cervical and thoracic SMT for the treatment of infant colic, the mother called the clinic to say the baby had been crying since the treatment. The intern spoke to the mother and stated that it as unlikely that the treatment had caused any harm, but if she was concerned, she should seek the advice of her general practitioner. The mother was satisfied with this and said that the crying was probably because of constipation. That evening, the baby slept better than usual, and the mother returned and completed the course of care for her child.
3	Female	6	The parent's returned to the clinic a few hours after the first treatment with cervical spine SMT (in treatment of infant colic) stating that they thought that the baby had a "head tilt" since the adjustment. The tutor examined the child and found full cervical range of motion with no antalgic posture. The parents were satisfied with this, did not feel there was any reaction from treatment, and continued care.
4	Female	7	The mother reported that the baby cried a lot after the first visit for cervical spinal SMT for the condition of infant colic, went to sleep for 2 hours, and awoke and continued to cry. She attended the clinic for 3 more visits and then self-discharged. When telephoned, she said the baby was "doing fine" and did not require more care.
5	Male	5	The parents told the intern that they would not attend the next (7th) visit because after the 6th visit of SMT for the condition of infant colic, the baby was restless and crying for almost 8 hours. They stated they did not wish to continue with treatment.
6	Male	17	On the 25th visit of a child who had been closely monitored since birth trauma, the intern adjusted the pelvis and the baby began to cry instantly. The mother felt that this was a cry of pain. The intern brought a tutor in to examine the infant. The tutor performed a corrective adjustment to the ileum and the baby stopped crying. The mother telephoned later that day to say that the child was fine. The mother continued to bring her child for monitoring and care when required for the next several months.
7	Female	12	At the 11th visit consisting of cervical spine manipulation for the condition of kinematic imbalance due to suboccipital strain (KISS), the baby cried during the treatment and continued to cry upon returning home. The intern telephoned the mother the following day. She said that the baby was better, but she wished to stop treatment.

2.

after manual therapy[39 43] and three reported adverse events (worsening symptoms) in the control group.[33 34 37]

Using data from all the studies reporting adverse events, there were 1308 infants exposed to manual therapy and nine non-serious adverse events recorded, giving an incidence rate of seven non-serious events per 1000 infants. Conversely, there were 11 non-serious adverse events in the infants not exposed to manual therapy (n=97), giving an incidence rate of around 110 per 1000 infants.

Figure 3 shows the meta-analysis for the RCTs, which was possible for four studies.[33 34 37 38] There was an overall RR of 0.12 (95% CI 0.12 to 0.66); that is, those who had manual therapy had an 88% reduced risk of having an adverse event compared with those who did not have manual therapy.
